Data Mining Classification: Basic Concepts, Decision Trees, and Model Evaluation

Lecture Notes for Chapter 4

Introduction to Data MiningbyTan, Steinbach, Kumar

Classification: Definition

- **•** Given a collection of records (*training set*)
	- – Each record contains a set of *attributes*, one of the attributes is the *class*.
- Find a *model* for class attribute as a function of the values of other attributes.
- Goal: previously unseen records should be assigned a class as accurately as possible.
	- – ^A*test set* is used to determine the accuracy of the model. Usually, the given data set is divided into training and test sets, with training set used to build the model and test set used to validate it.

Illustrating Classification Task

Examples of Classification Task

- **Predicting tumor cells as benign or malignant**
- Classifying credit card transactions as legitimate or fraudulent

- Classifying secondary structures of protein as alpha-helix, beta-sheet, or random coil
- **Categorizing news stories as finance,** weather, entertainment, sports, etc

Classification Techniques

- Decision Tree based Methods
- Rule-based Methods
- Memory based reasoning
- **Neural Networks**
- Naïve Bayes and Bayesian Belief Networks
- Support Vector Machines

Example of a Decision Tree

Training Data

Model: Decision Tree

Another Example of Decision Tree

There could be more than one tree that fits the same data!

Decision Tree Classification Task

Decision Tree Induction

- Many Algorithms:
	- $-$ Hunt's Algorithm (one of the earliest)
	- CART
	- –ID3, **C4.5** (**J48** in WEKA)
	- $-$ SLIQ,SPRINT

General Structure of Hunt's Algorithm

- Let D_t be the set of training records that reach a node t
- **General Procedure:**
	- $-$ If D_t contains records that belong the same class y_t , then t is a leaf node labeled as y_t
	- $-$ If D_t is an empty set, then t is a leaf node labeled by the default class, y_d
	- $-$ If D_t contains records that belong to more than one class, use an attribute test to split the data into smaller subsets. Recursively apply the procedure to each subset.

Tree Induction

- Greedy strategy.
	- Split the records based on an attribute test that optimizes certain criterion.
- Issues
	- – $-$ Determine how to split the records
		- ◆ How to specify the attribute test condition?
		- ◆ How to determine the best split?
	- – $-$ Determine when to stop splitting

Tree Induction

- Greedy strategy.
	- Split the records based on an attribute test that optimizes certain criterion.
- Issues
	- – $-$ Determine how to split the records ◆ How to specify the attribute test condition?
		- ◆ How to determine the best split?
	- – $-$ Determine when to stop splitting

How to Specify Test Condition?

- Depends on attribute types
	- Nominal
	- Ordinal
	- –Continuous
- Depends on number of ways to split
	- 2-way split
	- –Multi-way split

Splitting Based on Nominal Attributes

 Multi-way split: Use as many partitions as distinct values.

• Binary split: Divides values into two subsets. Need to find optimal partitioning.

Splitting Based on Continuous Attributes

Tree Induction

- Greedy strategy.
	- Split the records based on an attribute test that optimizes certain criterion.
- Issues
	- – $-$ Determine how to split the records
		- ◆ How to specify the attribute test condition?
		- ◆ How to determine the best split?
	- – $-$ Determine when to stop splitting

How to determine the Best Split

Which test condition is the best?

How to determine the Best Split

- Greedy approach:
	- Nodes with homogeneous class distribution are preferred
- Need a measure of node impurity:

Measures of Node Impurity

● Gini Index

● Entropy

Misclassification error

How to Find the Best Split

Measure of Impurity: GINI

• Gini Index for a given node t :

$$
GINI(t) = 1 - \sum_{j} [p(j \mid t)]^2
$$

(NOTE: *p(j | t)* is the relative frequency of class j at node t).

- $-$ Maximum (1 1/n_c) when records are equally $-$ distributed among all classes implying loast distributed among all classes, implying least interesting information
- – Minimum (0.0) when all records belong to one class, implying most interesting information

Examples for computing GINI

$$
GINI(t) = 1 - \sum_{j} [p(j | t)]^2
$$

$$
P(C1) = 1/6 \qquad P(C2) = 5/6
$$

Gini = 1 - (1/6)² - (5/6)² = 0.278

$$
P(C1) = 2/6 \qquad P(C2) = 4/6
$$

Gini = 1 - (2/6)² - (4/6)² = 0.444

Splitting Based on GINI

- Used in CART, SLIQ, SPRINT.
- When a node p is split into k partitions (children), the quality of split is computed as,

$$
GINI_{split} = \sum_{i=1}^{k} \frac{n_i}{n} GINI(i)
$$

where, n_i = number of records at child i, ⁿ = number of records at node p.

Binary Attributes: Computing GINI Index

- Splits into two partitions
- **Effect of Weighing partitions:**
	- $-$ Larger and Purer Partitions are sought for.

Categorical Attributes: Computing Gini Index

- For each distinct value, gather counts for each class in the dataset
- Use the count matrix to make decisions

Continuous Attributes: Computing Gini Index

- Use Binary Decisions based on one value
- **Several Choices for the splitting value**
	- Number of possible splitting values = Number of distinct values
- Each splitting value has a count matrix associated with it
	- Class counts in each of the partitions, A < v and A \geq v
- **•** Simple method to choose best **v**
	- For each v, scan the database to gather count matrix and compute its Gini index
	- Computationally Inefficient! Repetition of work.

Continuous Attributes: Computing Gini Index...

- **•** For efficient computation: for each attribute,
	- $-$ Sort the attribute on values
	- Linearly scan these values, each time updating the count matrix and computing gini index
	- Choose the split position that has the least gini index

Alternative Splitting Criteria based on INFO

● Entropy at a given node t:

$$
Entropy(t) = -\sum_{j} p(j | t) \log p(j | t)
$$

(NOTE: $p(j | t)$ is the relative frequency of class j at node t).

–Measures homogeneity of a node.

- \bullet Maximum (log n_c) when records are equally distributed among all classes implying least information
- -Minimum (0.0) when all records belong to one class, implying most information
- Entropy based computations are similar to the GINI index computations

Examples for computing Entropy

$$
Entropy(t) = -\sum_{j} p(j | t) \log_{2} p(j | t)
$$

P(C1) = 0/6 = 0 P(C2) = 6/6 = 1 Entropy = – 0 log 0 – 1 log 1 = – 0 – 0 = 0

 $P(C1) = 1/6$ $P(C2) = 5/6$ **Entropy = – (1/6) log 2 (1/6) – (5/6) log 2 (1/6) = 0.65**

 $P(C1) = 2/6$ $P(C2) = 4/6$ **Entropy = – (2/6) log 2 (2/6) – (4/6) log 2 (4/6) = 0.92**

Splitting Based on INFO...

 \bullet Information Gain:

$$
\overline{GAIN}_{\text{split}} = Entropy(p) - \left(\sum_{i=1}^{k} \frac{n_i}{n} Entropy(i)\right)
$$

Parent Node, p is split into k partitions;

n_i is number of records in partition i

- Measures Reduction in Entropy achieved because of the split. Choose the split that achieves most reduction (maximizes GAIN)
- Used in ID3 and C4.5
- Disadvantage: Tends to prefer splits that result in large number of partitions, each being small but pure.

Splitting Criteria based on Classification Error

Classification error at a node t :

$$
Error(t) = 1 - \max_i P(i \mid t)
$$

Measures misclassification error made by a node.

- Maximum $(1 1/n_c)$ when records are equally distributed among all classes, implying least interesting information
- Minimum (0.0) when all records belong to one class, implying most interesting information

Examples for Computing Error

$$
Error(t) = 1 - \max_i P(i \mid t)
$$

$$
P(C1) = 0/6 = 0 \qquad P(C2) = 6/6 = 1
$$

Error = 1 – max (0, 1) = 1 – 1 = 0

$$
P(C1) = 1/6
$$
 $P(C2) = 5/6$
Error = 1 – max (1/6, 5/6) = 1 – 5/6 = 1/6

$$
P(C1) = 2/6 \qquad P(C2) = 4/6
$$

Error = 1 – max (2/6, 4/6) = 1 – 4/6 = 1/3

Comparison among Splitting Criteria

For a 2-class problem:

Tree Induction

- Greedy strategy.
	- Split the records based on an attribute test that optimizes certain criterion.
- Issues
	- – $-$ Determine how to split the records
		- ◆ How to specify the attribute test condition?
		- ◆ How to determine the best split?
	- – $-$ Determine when to stop splitting

Stopping Criteria for Tree Induction

- Stop expanding a node when all the records belong to the same class
- Stop expanding a node when all the records have similar attribute values
- Early termination (to be discussed later)

Decision Tree Based Classification

Advantages:

- $-$ Inexpensive to construct
- $-$ Extremely fast at classifying unknown records
- – $-$ Easy to interpret for small-sized trees
- Accuracy is comparable to other classification techniques for many simple data sets

Example: C4.5

- Simple depth-first construction.
- Uses Information Gain
- Sorts Continuous Attributes at each node.
- Needs entire data to fit in memory.
- Unsuitable for Large Datasets.
	- –Needs out-of-core sorting.
- You can download the software from: http://www.cse.unsw.edu.au/~quinlan/c4.5r8.tar.gz

Underfitting and Overfitting (Example)

500 circular and 500 triangular data points.

Circular points:

0.5 ≤ **sqrt(x¹²+x2²)** ≤**1**

Triangular points:sqrt(x1²+x22) > 0.5 orsqrt(x1²+x22) < 1

Underfitting and Overfitting

Underfitting: when model is too simple, both training and test errors are large

Overfitting due to Noise

Decision boundary is distorted by noise point

Overfitting due to Insufficient Examples

Lack of data points in the lower half of the diagram makes it difficult to predict correctly the class labels of that region

- Insufficient number of training records in the region causes the decision tree to predict the test examples using other training records that are irrelevant to the classification task

Notes on Overfitting

- Overfitting results in decision trees that are more complex than necessary
- **Training error no longer provides a good estimate** of how well the tree will perform on previously unseen records
- Need new ways for estimating errors
- Given two models of similar generalization errors, one should prefer the simpler model over the more complex model
- For complex models, there is a greater chance that it was fitted accidentally by errors in data
- Therefore, one should include model complexity when evaluating a model

How to Address Overfitting

- Pre-Pruning (Early Stopping Rule)
	- – $-$ Stop the algorithm before it becomes a fully-grown tree
	- $-$ Typical stopping conditions for a node:
		- ◆ Stop if all instances belong to the same class
		- Stop if all the attribute values are the same
	- – More restrictive conditions:
		- ◆ Stop if number of instances is less than some user-specified threshold
		- ◆ Stop if class distribution of instances are independent of the available features (e.g., using χ 2 test)
		- ◆ Stop if expanding the current node does not improve impurity measures (e.g., Gini or information gain).

How to Address Overfitting…

● Post-pruning

- $-$ Grow decision tree to its entirety
- Trim the nodes of the decision tree in a bottom-up fashion
- If generalization error improves after trimming, replace sub-tree by a leaf node.
- – Class label of leaf node is determined from majority class of instances in the sub-tree
- Can use MDL for post-pruning

Decision Boundary

- **Border line between two neighboring regions of different classes is known as decision boundary**
- **Decision boundary is parallel to axes because test condition involves a single attribute at-a-time**

Oblique Decision Trees

- **Test condition may involve multiple attributes**
- **More expressive representation**
- **Finding optimal test condition is computationally expensive**

- Metrics for Performance Evaluation
	- $-$ How to evaluate the performance of a model?
- Methods for Performance Evaluation
	- How to obtain reliable estimates?
- Methods for Model Comparison
	- –- How to compare the relative performance among competing models?

Model Evaluation

Metrics for Performance Evaluation

- $-$ How to evaluate the performance of a model?
- Methods for Performance Evaluation
	- How to obtain reliable estimates?
- Methods for Model Comparison
	- –- How to compare the relative performance among competing models?

Metrics for Performance Evaluation

Focus on the predictive capability of a model

- Rather than how fast it takes to classify or build models, scalability, etc.
- Confusion Matrix:

a: TP (true positive)

- **b: FN (false negative)**
- **c: FP (false positive)**
- **d: TN (true negative)**

Metrics for Performance Evaluation…

Most widely-used metric:

$$
Accuracy = \frac{a+d}{a+b+c+d} = \frac{TP + TN}{TP + TN + FP + FN}
$$

Limitation of Accuracy

- Consider a 2-class problem
	- Number of Class 0 examples = 9990
	- Number of Class 1 examples = 10
- If model predicts everything to be class 0, accuracy is 9990/10000 = 99.9 %
	- Accuracy is mislaading haca Accuracy is misleading because model does not detect any class 1 example

C(i|j): Cost of misclassifying class j example as class i

Computing Cost of Classification

Accuracy = 80% $Cost = 3910$

Accuracy = 90% $Cost = 4255$

+

-

²⁵⁰ ⁴⁵

⁵ ²⁰⁰

PREDICTED CLASS

+

 -

Cost vs Accuracy

Accuracy is proportional to cost if1. $C(Yes|No) = C(No|Yes) = q$ 2. C(Yes|Yes)=C(No|No) = p

$$
N = a + b + c + d
$$

Accuracy = $(a + d)/N$

Cost = p (a + d) + q (b + c)= p (a + d) + q (N – a – d) = q N – (q – p)(a + d) = N [q – (q-p) ×Accuracy]

Cost-Sensitive Measures

Precision (p) =
$$
\frac{a}{a+c}
$$

\nRecall (r) = $\frac{a}{a+b}$
\nF - measure (F) = $\frac{2rp}{r+p} = \frac{2a}{2a+b+c}$

- Precision is biased towards C(Yes|Yes) & C(Yes|No)
- Recall is biased towards C(Yes|Yes) & C(No|Yes)
- F-measure is biased towards all except C(No|No)

Weighted Accuracy =
$$
\frac{w_1 a + w_4 d}{w_1 a + w_2 b + w_3 c + w_4 d}
$$

- Metrics for Performance Evaluation
	- $-$ How to evaluate the performance of a model?
- Methods for Performance Evaluation
	- How to obtain reliable estimates?
- Methods for Model Comparison
	- –- How to compare the relative performance among competing models?

Methods for Performance Evaluation

- How to obtain a reliable estimate of performance?
- Performance of a model may depend on other factors besides the learning algorithm:
	- Class distribution
	- – $-$ Cost of misclassification
	- – $-$ Size of training and test sets

Methods of Estimation

- Holdout
	- Reserve 2/3 for training and 1/3 for testing
- Random subsampling
	- $-$ Repeated holdout
- **Cross validation**
	- – $-$ Partition data into k disjoint subsets
	- – $-$ k-fold: train on k-1 partitions, test on the remaining one
	- Leave-one-out: k=n
- Stratified sampling
	- – $-$ oversampling vs undersampling
- Bootstrap
	- $-$ Sampling with replacement
