

DEVELOPMENT FRAMEWORK NODE.JS, NPM, GIT

Salvatore Rinzivillo

OBJECTIVES

- Setup a developing environment
 - Install Node.js and NPM
 - Install and configure Vue and @vue/cli
 - Configure and initialize a project
- Install and configure git
 - Create a repository and import project files
- IDEs
 - Fork, Git Desktop
 - WebStorm, VS Code

NODE.JS AND NPM

WHAT IS NODE.JS

- “An asynchronous event driven Javascript runtime”
 - Non-blocking, event-driven I/O operations
 - Lightweight and efficient for data-intensive applications
 - Distributed computation and load balancing
- Available for download at
<https://nodejs.org/>

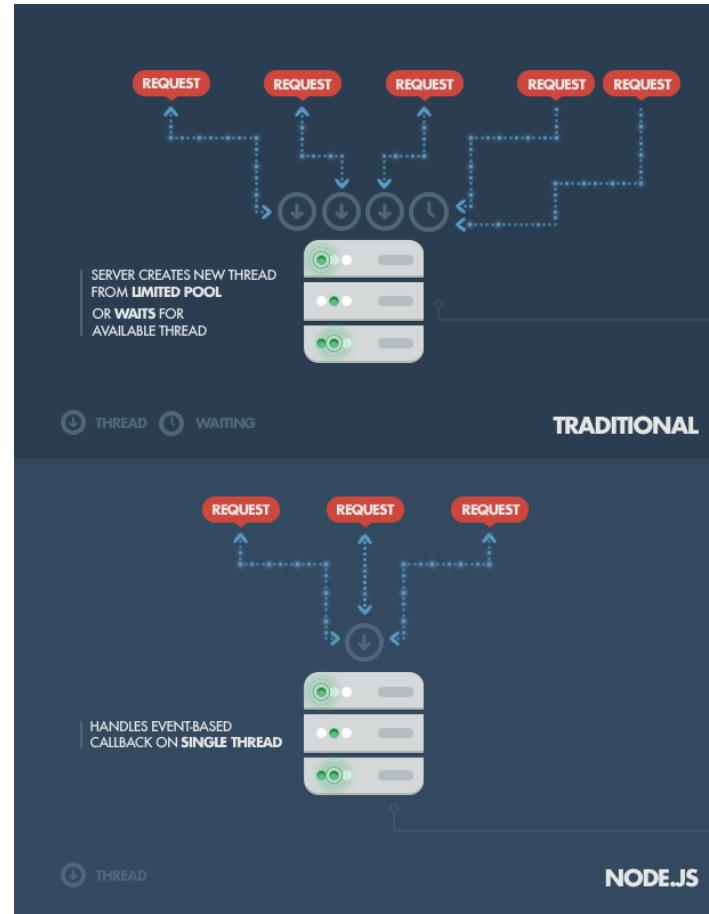

Image source: <https://www.toptal.com/nodejs/why-the-hell-would-i-use-node-js>

NPM - NODE PACKAGE MANAGER

- Node.js has a large library of public available, reusable components
- Components are available through a repository
- Manage libraries for global use and local projects
- Handle all dependencies

NPM - COMMANDS

- **npm init**
 - Initialize a project, creating a file **package.json**
- **npm install <module>**
 - Download and install module within the directory **node_modules**
 - ~~With the flag **--save**, add the module to the **package.json** list of dependencies~~
 - With the flag **--global** (or **-g**) the module is installed globally on the system

MOST USED PACKAGES

- Express: a web application development framework for node.js
- Lodash: general utilities for handling data structures in javascript
- http-server; webpack; babel
- Specifically for the course:
 - D3
 - Vega; Vega-lite
 - Bootstrap
 - Vue.js
 - ...

EXERCISE – CREATE A PROJECT WITH NODE.JS

- Demo

CONFIGURING VUE.JS AND @VUE/CLI

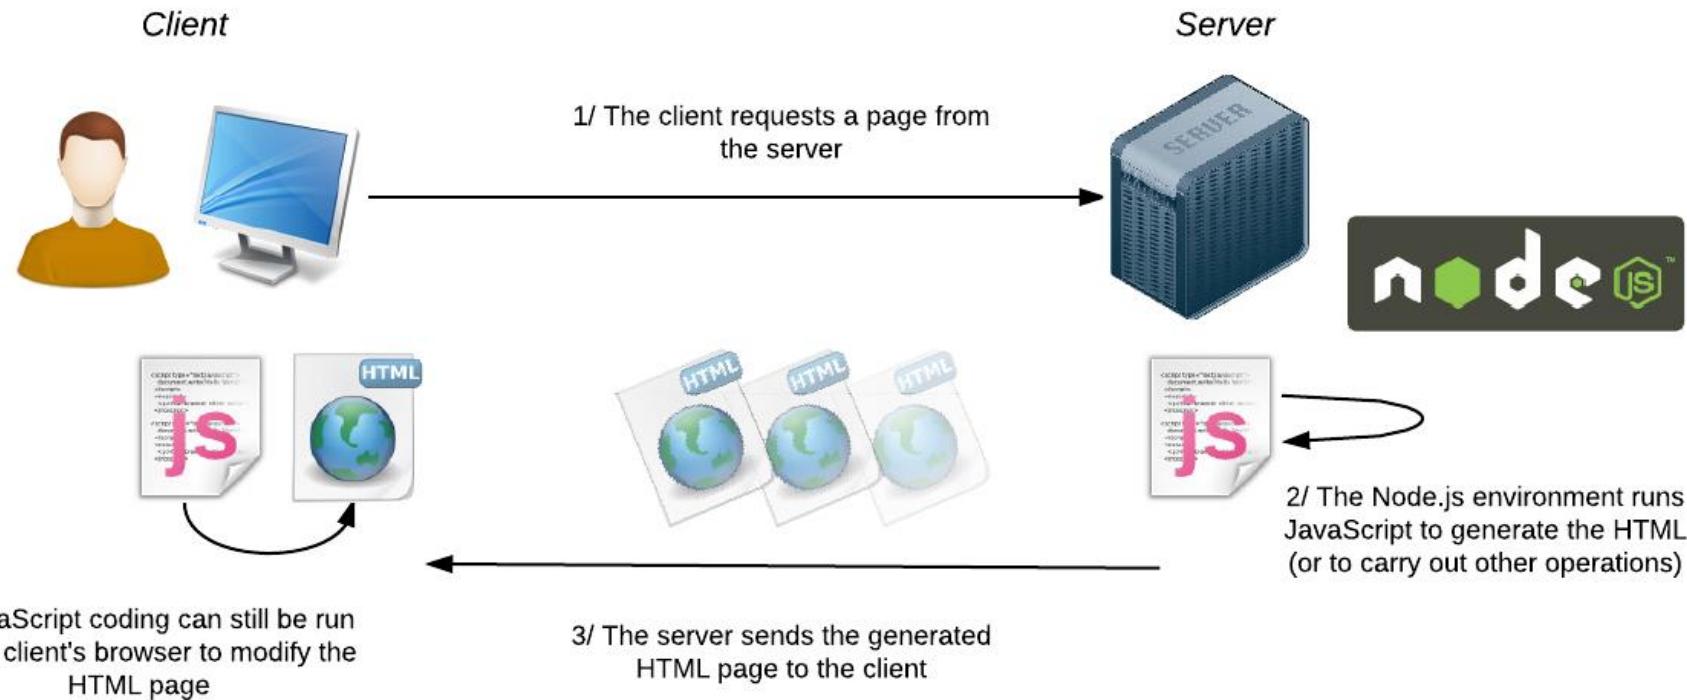

- `npm install -g @vue/cli`
 - Create a command to manage Vue.js projects
- `npm init vue@latest`
- `cd my-project`
- `npm install`
- `npm run dev`
- These commands create a skeleton project configured with Vue.js

WEB SERVER

WEB SERVER FOR NODE.JS

WEB SERVER IN NODE.JS

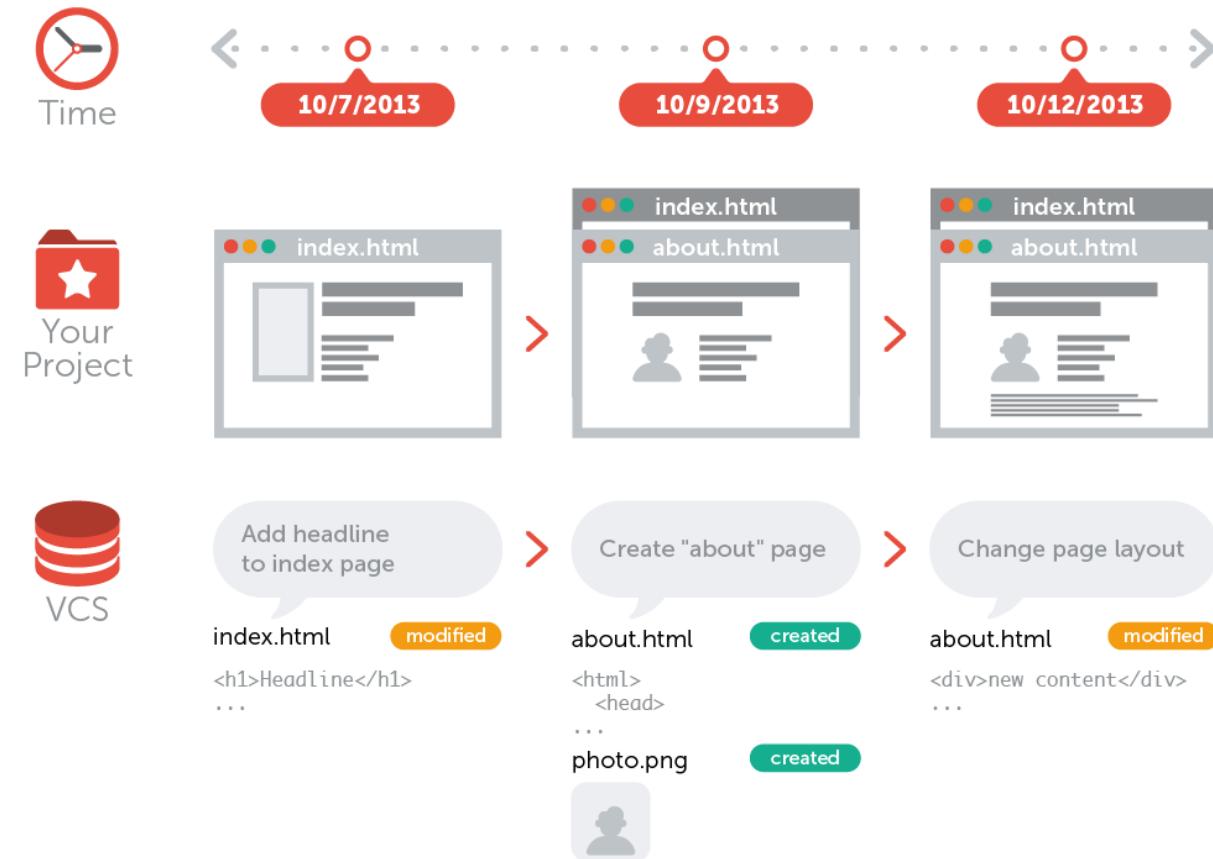

- There are several modules available for running a web server
- A very simple http server:
 - `npm install -g http-server`
- A more sophisticated application server:
 - `npm install -g express`

EXERCISE – USE HTTP-SERVER TO ACCESS OUR PROJECT

- Demo

VERSION CONTROL WITH GIT

WHAT IS VERSION CONTROL?

WHY USE A VERSION CONTROL SYSTEM?

- Collaboration
 - Any member of a team can work on any file at any time
 - Merge of contribution is handle by the VCS
- Storing versions
 - Tracking of changes through periodic saves of snapshots
 - Only one version of a project at any time
 - Other versions are packed within the VCS
- Restore previous versions
- Follow the development of the project
- Backup, when using external repositories

WHICH VCS? INTRODUCING GIT

- Download a client from public repositories
 - For example: GitHub, BitBucket
- Use clients specific for your OS
 - For example: brew install git (for MacOsX)
- Initial configuration
 - git config --global user.name "rinziv"
 - git config --global user.email "rinzivillo@isti.cnr.it"
 - git config --global

GIT - CREATING A REPOSITORY

- GIT handles two kinds of repositories
 - Local repository
 - Contained within a folder `.git` in the root of the project folder
 - Only one person access this repo
 - Remote repository
 - Located into a remote server
 - Locally stored within the `.git` folder
 - Team members work concurrently on remote repository

GIT - CREATE A LOCAL REPOSITORY

- Move within the project root directory
- Use `git init` to start versioning tracking
- The root of the project is called working copy
 - There is only one working copy at any moment
 - It is possible to update the current working copy with previous versions from the repository
- Some files (usually related to the OS) can be ignored for the versioning
 - Create a file called `.gitignore` in the root of the project folder
 - List the files to ignore within the file

GIT - CLONE A REMOTE REPOSITORY

- A remote repository have a URL of the form:
 - ssh://user@server/git-repo.git
 - user@server:git-repo.git
 - http://example.com/git-repo.git
 - https://example.com/git-repo.git
 - git://example.com/git-repo.git

GIT - COMMIT

- Commit operation save the snapshot of the working copy on the repository
 - `git add -A`
 - `git commit -m "Initial commit"`

GIT - STATUS OF THE PROJECT

- Each file within the project have one of the following state
 - **Untracked**: the file is not under version control. GIT do not track any change on this file
 - **Tracked**: GIT reports changes on these files
- **git status** reports the list of files within the project that have changed and those that are not tracked

GIT - STAGING AREA

Working Copy

Your Project's Files

Git watches tracked files
for new local modifications...

Tracked (and modified)

If a file was modified since it
was last committed, you can
stage & commit these changes

stage

Changes that are **not staged** will
not be committed & remain as
local changes until you stage &
commit or discard them

Untracked

Changes in untracked files aren't
watched. If you want them included
in version control, you have to tell
Git to start tracking them. If not, you
should consider ignoring them.

Staging Area

Changes included in
the Next Commit

Changes that were added to
the Staging Area will be
included in the next commit

commit

Local Repository

The ".git" Folder

All changes contained in a
commit are saved in the local
repository as a new revision

GIT – PREPARING THE STAGING AREA AND COMMIT

- Add the files to include in the staging area
 - `git add new-page.html index.html css/*`
 - `git rm error.html`
 - Check the status with: `git status`
- Commit changes
 - `git commit -m "Implement the new login box"`

WHEN TO COMMIT?

- Each commit should contains changes related to a single topic
- Save only completed work (for temporary saving use Stash)
- Test the project before committing
- Add descriptive message
- Commit often

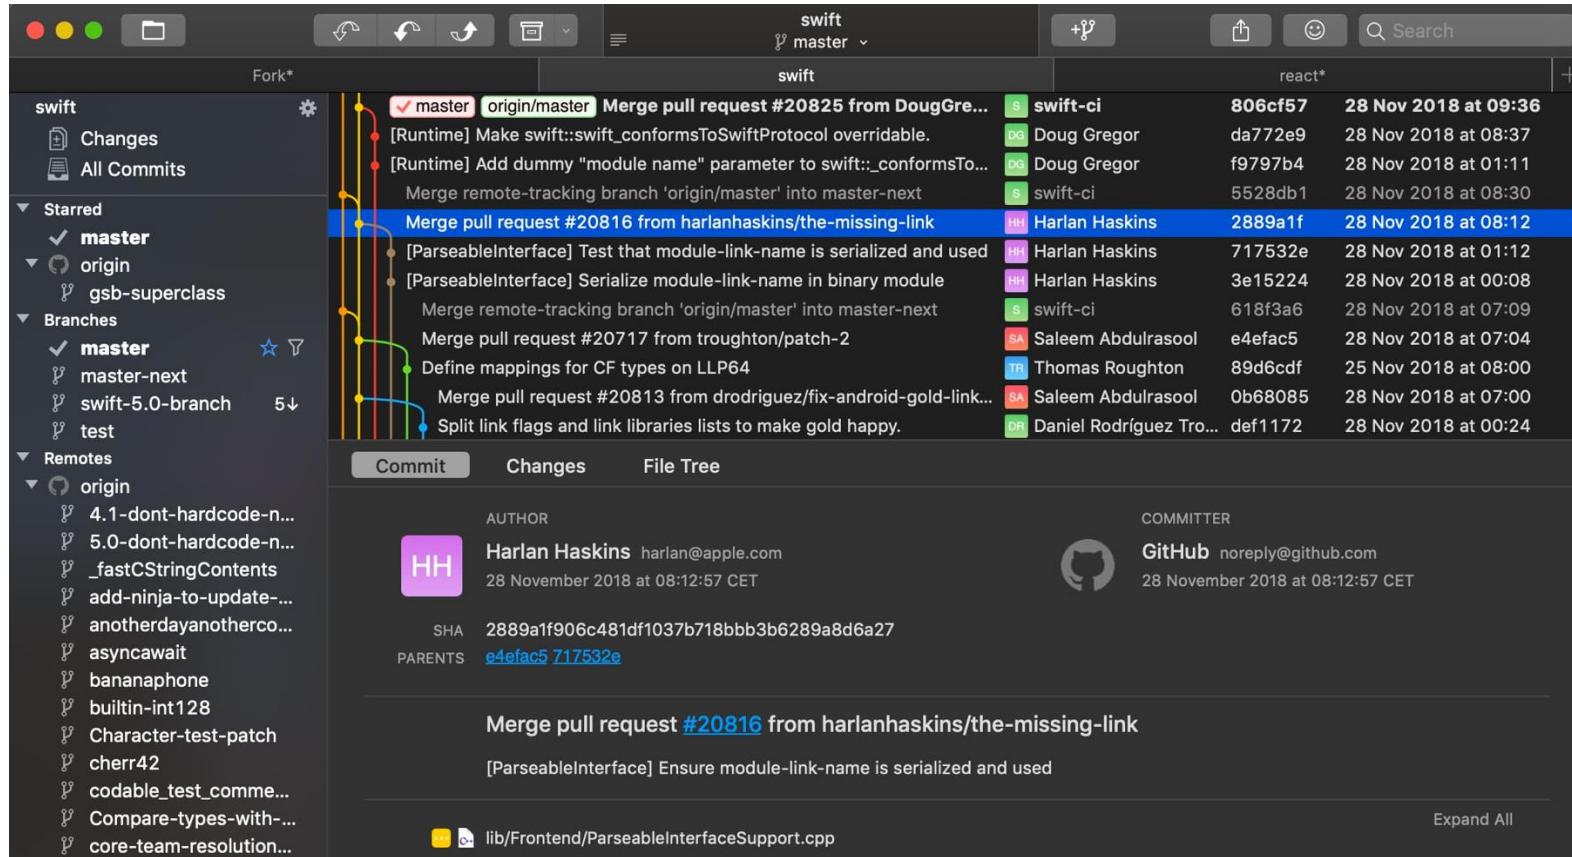

DESKTOP GUI VERSION

The screenshot shows a GitHub desktop application window. The repository is 'rinziv/CicloPI-Viz'. The current branch is 'master'. A pull request titled 'small changes to legend layout' by 'rinziv' is being reviewed. The commit message is 'small changes to legend layout'. The file being viewed is 'assets/js/script.js'. The code diff highlights changes made to the script. The changes involve modifying the width of an SVG element and creating a data legend function.
