## Shortest paths application: Currency conversion

**Currency conversion.** Given currencies and exchange rates, what is best way to convert one ounce of gold to US dollars?

- 1 oz. gold  $\Rightarrow$  \$327.25.
- 1 oz. gold  $\Rightarrow$  £208.10  $\Rightarrow$  \$327.00. [  $208.10 \times 1.5714$  ]
- 1 oz. gold  $\Rightarrow$  455.2 Francs  $\Rightarrow$  304.39 Euros  $\Rightarrow$  \$327.28. [  $455.2 \times .6677 \times 1.0752$  ]

| Currency     | £        | Euro     | ¥         | Franc    | \$       | Gold    |
|--------------|----------|----------|-----------|----------|----------|---------|
| UK Pound     | 1.0000   | 0.6853   | 0.005290  | 0.4569   | 0.6368   | 208.100 |
| Euro         | 1.4599   | 1.0000   | 0.007721  | 0.6677   | 0.9303   | 304.028 |
| Japanese Yen | 189.050  | 129.520  | 1.0000    | 85.4694  | 120.400  | 39346.7 |
| Swiss Franc  | 2.1904   | 1.4978   | 0.011574  | 1.0000   | 1.3941   | 455.200 |
| US Dollar    | 1.5714   | 1.0752   | 0.008309  | 0.7182   | 1.0000   | 327.250 |
| Gold (oz.)   | 0.004816 | 0.003295 | 0.0000255 | 0.002201 | 0.003065 | 1.0000  |

## Shortest paths application: Currency conversion

### Graph formulation.

- Vertex = currency.
- Edge = transaction, with weight equal to exchange rate.
- Find path that maximizes product of weights.

## Shortest paths application: Currency conversion

Reduce to shortest path problem by taking logs

- Let weight( $v-w$ ) =  $-\lg$  (exchange rate from currency  $v$  to  $w$ )
- multiplication turns to addition
- Shortest path with costs  $c$  corresponds to best exchange sequence.

Challenge. Solve shortest path problem with **negative** weights.

## Shortest paths with negative weights: failed attempts

Dijkstra. Doesn't work with negative edge weights.

Dijkstra selects vertex 3 immediately after 0.  
But shortest path from 0 to 3 is  $0 \rightarrow 1 \rightarrow 2 \rightarrow 3$ .

Re-weighting. Adding a constant to every edge weight also doesn't work.

Adding 9 to each edge changes the shortest path because it adds 9 to each segment, wrong thing to do for paths with many segments.

Bad news: need a different algorithm.

## Shortest paths with negative weights: **negative cycles**

**Negative cycle.** Directed cycle whose sum of edge weights is negative.

### Observations.

- If negative cycle  $C$  on path from  $s$  to  $t$ , then shortest path can be made **arbitrarily negative** by spinning around cycle
- There exists a shortest  $s-t$  path that is simple.

**Worse news:** need a different **problem**

## Shortest paths with negative weights

Problem 1. Does a given digraph contain a negative cycle?

Problem 2. Find the shortest simple path from  $s$  to  $t$ .

Bad news: Problem 2 is intractable

Good news: Can solve problem 1 in  $O(VE)$  steps

Good news: Same algorithm solves problem 2 if no negative cycle

### Bellman-Ford algorithm

- detects a negative cycle if any exist
- finds shortest simple path if no negative cycle exists

## Edge relaxation

For all  $v$ ,  $\text{dist}[v]$  is the length of some path from  $s$  to  $v$ .

Relaxation along edge  $e$  from  $v$  to  $w$ .

- $\text{dist}[v]$  is length of some path from  $s$  to  $v$
- $\text{dist}[w]$  is length of some path from  $s$  to  $w$
- if  $v-w$  gives a shorter path to  $w$  through  $v$ , update  $\text{dist}[w]$  and  $\text{pred}[w]$

```
if (dist[w] > dist[v] + e.weight())  
{  
    dist[w] = dist[v] + e.weight();  
    pred[w] = v;  
}
```

Relaxation sets  $\text{dist}[w]$  to the length of a shorter path from  $s$  to  $w$  (if  $v-w$  gives one)

## Shortest paths with negative weights: dynamic programming algorithm

A simple solution that works!

- Initialize  $\text{dist}[v] = \infty$ ,  $\text{dist}[s] = 0$ .
- Repeat  $v$  times: relax each edge  $e$ .

```
phase i
for (int i = 1; i <= G.V(); i++)
  for (int v = 0; v < G.V(); v++)
    for (Edge e : G.adj(v))
      {
        int w = e.to();
        if (dist[w] > dist[v] + e.weight()) ← relax v-w
        {
          dist[w] = dist[v] + e.weight()
          pred[w] = e;
        }
      }
```

## Shortest paths with negative weights: dynamic programming algorithm

Running time proportional to  $E V$

Invariant. At end of phase  $i$ ,  $\text{dist}[v] \leq$  length of any path from  $s$  to  $v$  using at most  $i$  edges.

Theorem. If there are no negative cycles, upon termination  $\text{dist}[v]$  is the length of the shortest path from  $s$  to  $v$ .

←  $\text{pred}[]$  gives the shortest paths

## Shortest paths with negative weights: Bellman-Ford-Moore algorithm

Observation. If  $\text{dist}[v]$  doesn't change during phase  $i$ ,  
no need to relax any edge leaving  $v$  in phase  $i+1$ .

FIFO implementation.

Maintain queue of vertices whose distance changed.

be careful to keep at most one copy of each vertex on queue

Running time.

- still could be proportional to  $EV$  in worst case
- much faster than that in practice

## Negative cycle detection

If there is a negative cycle reachable from  $s$ ,  
Bellman-Ford-Moore gets stuck in loop, updating vertices in cycle.

Finding a negative cycle. If **any** vertex  $v$  is updated in phase  $v$ ,  
there exists a negative cycle, and we can trace back  $\text{pred}[v]$  to find it.

## Negative cycle detection

**Goal.** Identify a negative cycle (reachable from any vertex).

**Solution.** Add 0-weight edge from artificial source  $s$  to each vertex  $v$ .  
Run Bellman-Ford from vertex  $s$ .
